

## FEATURES

- Meets CCITT G.703 Pulse Mask Template for 2.048Mbps (E1) Rates
- Transmitter and Receiver Interfaces Can Be:
  - Single Ended, 75Ω Capacitive or Transformer Coupled
  - Balanced, 100Ω or 120Ω Transformer Coupled
- Minimum Return Loss is 20dB (Receive) and 18dB (Transmit), Exceeds G.703 and ETSI 300 166 Specifications
- Bipolar Outputs Can Be Disabled Individually (High Z Outputs)
- System Interface is TTL Compatible on Digital Input and TTL/CMOS Compatible on Digital Output Pins

- Individual Channel Loss of Signal Detection, Local and Remote Digital Loopback
- Low Power, CMOS Technology
- Over-Temperature Protection

## APPLICATIONS

- Multi-Line E1 Interface Cards
- E1 Network Equipment
  - Multiplexers
  - Cross Connects
  - Switching Systems
- Fault Tolerant Systems

## GENERAL DESCRIPTION

The XR-T5793 is an optimized line interface unit, built using low power CMOS technology. This device contains four independent E1 channels for primary rate, PCM applications up to 2.048Mbps. Each channel performs the driver and receiver functions necessary to convert bipolar signals to TTL/CMOS compatible logic levels and vice versa. The device supports single ended or balanced line interfaces on each channel, thereby providing the user an option of reducing system cost and board space by replacing the transformer with a capacitor.

Each of the four drivers can be independently disabled, allowing maximum flexibility in system power management. Output pulses are fully CCITT G.703 compliant. Moreover, the return loss is at least 18dB over a frequency range of 51kHz to 3.072MHz.

The slicing circuit in the receive path is able to tolerate a maximum of 12dB of cable loss with a minimum input

sensitivity of 600mV over the operating temperature range. Return loss on the receive interfaces is minimum 20dB from 51kHz to 3.072MHz.

Local and remote loopbacks can be performed on any of the four channels. A separate loss of signal (LOS) detection circuitry and a LOS pin is provided for each input.

The XR-T5793 is targeted for multi-line E1 line card applications where real estate and low power consumption are critical. Also, the device may be used in T1 applications (1.544Mbps) which do not require meeting the DSX-1 cross connect pulse template. The XR-T5793 is pin compatible with the XR-T5794, which supports a fifth channel. The fifth channel is for redundancy and dedicated monitoring on any of the eight bipolar paths.

**SYSTEM DESCRIPTION**

This device is a quad E1 transceiver which provides electrical interface for 2.048Mbps applications. Its unique architecture includes four receiver circuits that convert CCITT G.703 compliant bipolar signals to TTL compatible logic levels. Likewise, in the other direction, four transmitters translate TTL compatible logic levels to G.703 compatible bipolar signals.

This device supports two different types of loopback functions. Each of four channels can be independently looped either in local or remote sides digitally. The remote loopback is performed between the receiver input and transmitter output. To activate the remote loopback on channel n, LOOPENn and LPMODn inputs are driven high. Local loopback on channel n, can be established similarly by driving LOOPENn high and clearing LPMODn inputs. More than one channel can be tested simultaneously.

**RECEIVERS**

Each of the four identical E1 line receivers will accept bipolar signals meeting the CCITT G.703 pulse mask requirements. Each input stage consists of a slicing circuitry which samples the incoming pulses at a fixed percentage of the signals maximum amplitude. The slicing voltage level is generated using a precision peak detector. The receiver section can tolerate up to 12dB of line loss (measured at 1.024MHz).

A loss of signal (LOS) is detected on any inputs by input fail circuitry. There is an independent LOS pin dedicated for each of the receivers. The LOS detection is based on signal energy instead of number of zeros.

A balanced signal (100Ω or 120Ω) must be coupled by a transformer. An unbalanced signal (75Ω) may be coupled via capacitor or a transformer.

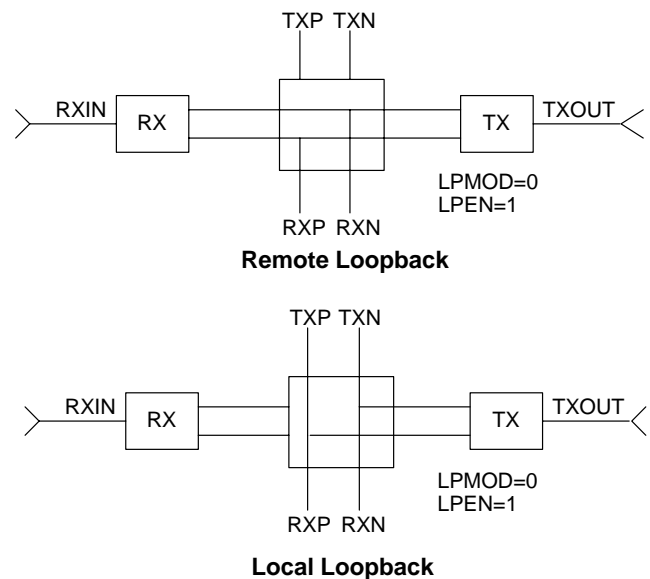

**TRANSMITTERS**

This device contains four identical CCITT G.703 compliant transmitters which meet the return loss requirements. Each transmitter is a single-ended voltage

driver. External resistors are used to maintain an accurate source impedance that has a high return loss to the transformer or the capacitor. Each of the drivers can be individually disabled, this is required in fault tolerant applications where redundancy is a requirement. During power-down mode of operation the bipolar outputs can be disabled.

To protect the data integrity during a brownout, the output pulse amplitudes are reduced by a factor of 25% if the supply drops below an internally set limit.

Transmission is possible either with or without a clock. If a clock is used, the transmit input data must consist of full-width NRZ pulses, and the transmitter output pulse width is determined by the duty cycle of the clock. If the transmit clock is tied high, the transmitter output pulses are determined by the input data pulse width. In this mode, RZ data must be supplied to the device.

**Figure 4. Loopback Configurations**

## Output Transformer Selection

The 1:1.265 ratio output transformer is recommended for the XR-T5793 because this ratio gives the best possible transmitter output return loss for 120Ω balanced E1 service. However, other transformers may provide an adequate return loss for many applications. The two characteristics that determine series build-out resistor requirements are:

- Driver output impedance is less than 5Ω.
- $V_s$ , which is the driver open circuit output voltage, is 4.5V peak.

The following method may be used to determine transformer suitability for a given use.

1. List the application requirements.

Transformer ratio = 1:n

$V_o$  = Peak output pulse amplitude

$R_L$  = Load resistance

Figure 5. Equivalent Impedance Schematic

2. Calculate equivalent output voltage and load resistance without the transformer.

$$R_{eq} = \frac{R_L}{n^2} \quad V_{eq} = \frac{V_o}{n}$$

Figure 6. Equivalent Simplified Schematic

3. Calculate the source resistance,  $R_s$ .

$$R_s = R_{eq} \left( \frac{V_s}{V_{eq}} - 1 \right)$$

4. Now calculate the theoretical return loss.

$$\text{Return Loss} = 20 \log \left( \frac{R_{eq} + R_s}{R_{eq} - R_s} \right)$$

The calculation given below uses the recommended 1:1.265 ratio transformer as an example:

Transformer Ratio = 1:1.265

$V_o$  = 3.0V Peak

$R_L$  = 120Ω

$$R_{eq} = \frac{R_L}{n^2} = \frac{120}{1.6} = 75\Omega$$

$$V_{eq} = \frac{V_o}{n} = \frac{3.0}{1.265} = 2.37V$$

$$R_s = R_{eq} \left( \frac{V_s}{V_{eq}} - 1 \right) = 75 \left( \frac{4.5}{2.37} - 1 \right) = 67.4\Omega$$

(Datasheet specifies standard value of 68Ω)

Calculate the theoretical return loss to determine if the transformer is acceptable.

$$\text{Return Loss} = 20 \log \left( \frac{75 + 67.4}{75 - 67.4} \right) = 25.5dB$$

**Note:** V corresponds to the nominal peak value
