

Flash Memory Programming Specification

1.0 DEVICE OVERVIEW

This document includes the programming specifications for the following devices:

- PIC18F13K22 PIC18LF13K22
- PIC18F14K22 PIC18LF14K22

2.0 PROGRAMMING OVERVIEW

The PIC18F1XK22/LF1XK22 devices can be programmed using either the high-voltage In-Circuit Serial ProgrammingTM (ICSPTM) method or the low-voltage ICSP method. Both methods can be done with the device in the users' system. The low-voltage ICSP method is slightly different than the high-voltage method and these differences are noted where applicable. The PIC18F1XK22 devices operate from 1.8 to 5.5 volts and the PIC18LF1XK22 devices operate from 1.8 to 3.6 volts. All other aspects of the PIC18F1XK22 with regards to the PIC18LF1XK22 devices are identical.

2.1 Hardware Requirements

In High-Voltage ICSP mode, the PIC18F1XK22/ LF1XK22 devices require two programmable power supplies: one for VDD and one for MCLR/VPP/RA3. Both supplies should have a minimum resolution of 0.25V. Refer to Section 8.0 "AC/DC Characteristics Timing Requirements for Program/Verify Test Mode" for additional hardware parameters.

2.1.1 LOW-VOLTAGE ICSP PROGRAMMING

In Low-Voltage ICSP mode, the PIC18F1XK22/ LF1XK22 devices can be programmed using a single VDD source in the operating range. The MCLR/VPP/ RA3 does not have to be brought to a different voltage, but can instead be left at the normal operating voltage. Refer to Section 8.0 "AC/DC Characteristics Timing Requirements for Program/Verify Test Mode" for additional hardware parameters.

2.1.1.1 Single-Supply ICSP Programming

The LVP bit in Configuration register, CONFIG4L, enables single-supply (low-voltage) ICSP programming. The LVP bit defaults to a '1' (enabled) from the factory.

If Single-Supply Programming mode is not used, the LVP bit can be programmed to a '0' and RC3/PGM becomes a digital I/O pin. However, the LVP bit may only be programmed by entering the High-Voltage ICSP mode, where MCLR/VPP/RA3 is raised to VIHH. Once the LVP bit is programmed to a '0', only the High-Voltage ICSP mode is available and only the High-Voltage ICSP mode can be used to program the device.

- Note 1: The High-Voltage ICSP mode is always available, regardless of the state of the LVP bit, by applying VIHH to the MCLR/ VPP/RA3 pin.
 - 2: While in Low-Voltage ICSP mode, the RC3 pin can no longer be used as a general purpose I/O.

2.2 Pin Diagrams

The pin diagrams for the PIC18F1XK22/LF1XK22 family are shown in Figure 2-1.

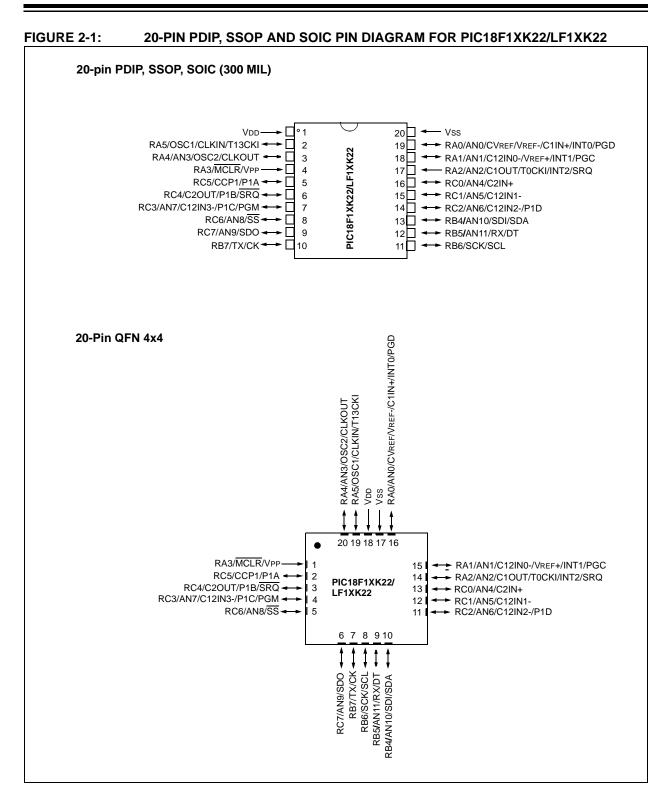

TABLE 2-1: PIN DESCRIPTIONS (DURING PROGRAMMING): PIC18F1XK22/LF1XK22

Pin Name	During Programming		
Fin Name	Pin Name	Pin Type	Pin Description
MCLR/Vpp/RA3	Vpp	Р	Programming Enable
VDD ⁽²⁾	Vdd	Р	Power Supply
VSS ⁽²⁾	Vss	Р	Ground
RC3	PGM	I	Low-Voltage ICSP [™] input when LVP Configuration bit equals '1' ⁽¹⁾
RA1	PGC	I	Serial Clock
RA0	PGD	I/O	Serial Data

Legend: I = Input, O = Output, P = Power

Note 1: See Figure 6-1 for more information.

2: All power supply (VDD) and ground (VSS) pins must be connected.

3.0 MEMORY MAPS

For the PIC18F14K22/LF14K22 device, the code memory space extends from 0000h to 03FFFh (16 Kbytes) in two 8-Kbyte blocks. For the PIC18F13K22/LF13K22 device, the code memory space extends from 0000h to 01FFFh (8 Kbytes) in two 4-Kbyte blocks.

For the PIC18F14K22/LF14K22 addresses 0000h through 0FFFh, however, define a "Boot Block" region that is treated separately from Block 0. For the PIC18F13K22/LF13K22 addresses 0000h through 07FFh, define the "Boot Block" region. All of these blocks define code protection boundaries within the code memory space. The size of the Boot Block in the PIC18F14K22/LF14K22 devices can be configured as 2K, or 4 Kbyte (see Figure 3-1). The size of the Boot

Block in the PIC18F13K22/LF13K22 devices can be configured as 1K, or 2 Kbytes (see Figure 3-1). This is done through the BBSIZ bit in the Configuration register, CONFIG4L. It is important to note that increasing the size of the Boot Block decreases the size of the Block 0.

TABLE 3-1:	IMPLEMENTATION OF CODE	
	MEMORY	

Device	Code Memory Size (Bytes)
PIC18F13K22/ LF13K22	000000h-001FFFh (8K)
PIC18F14K22/ LF14K22	000000h-003FFFh (16K)

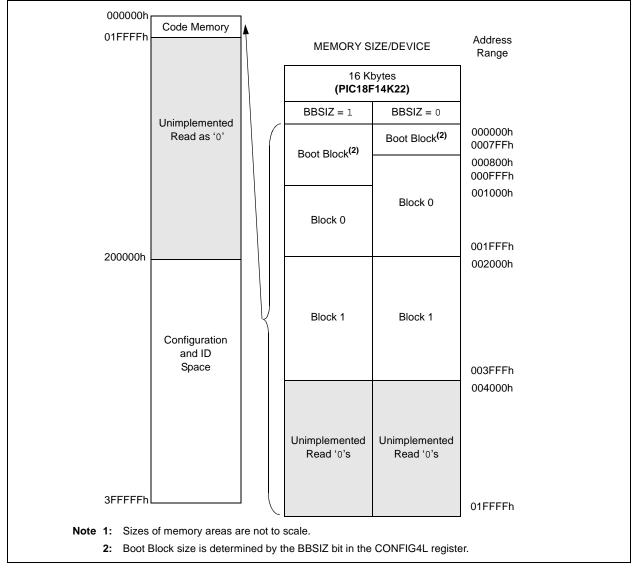

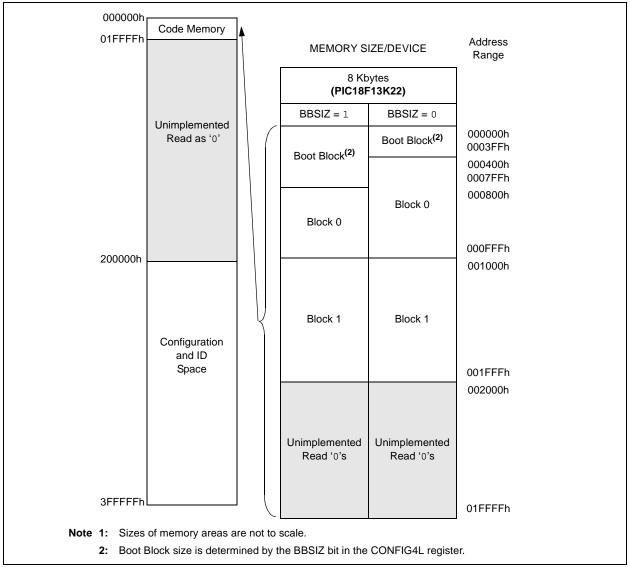

FIGURE 3-2: MEMORY MAP AND THE CODE MEMORY SPACE FOR PIC18F13K22/LF13K22 DEVICES⁽¹⁾

In addition to the code memory space, there are three blocks in the configuration and ID space that are accessible to the user through table reads and table writes. Their locations in the memory map are shown in Figure 3-3.

Users may store identification information (ID) in eight ID registers. These ID registers are mapped in addresses 200000h through 200007h. The ID locations read out normally, even after code protection is applied.

Locations 300001h through 30000Dh are reserved for the Configuration bits. These bits select various device options and are described in **Section 6.0** "**Configuration Word**". These Configuration bits read out normally, even after code protection.

Locations 3FFFFEh and 3FFFFFh are reserved for the device ID bits. These bits may be used by the programmer to identify what device type is being programmed and are described in **Section 6.0** "**Configuration Word**". These device ID bits read out normally, even after code protection.

3.0.1 MEMORY ADDRESS POINTER

Memory in the address space, 0000000h to 3FFFFh, is addressed via the Table Pointer register, which is comprised of three Pointer registers:

- TBLPTRU, at RAM address 0FF8h
- TBLPTRH, at RAM address 0FF7h
- TBLPTRL, at RAM address 0FF6h

TBLPTRU	TBLPTRH	TBLPTRL
Addr[21:16]	Addr[15:8]	Addr[7:0]

The 4-bit command, '0000' (core instruction), is used to load the Table Pointer prior to using any read or write operations.

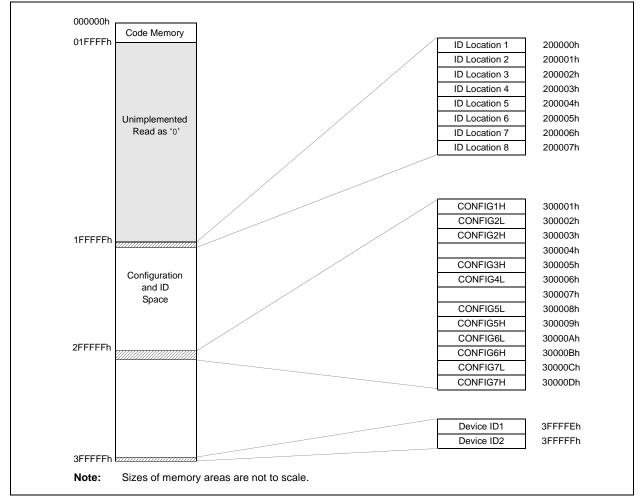

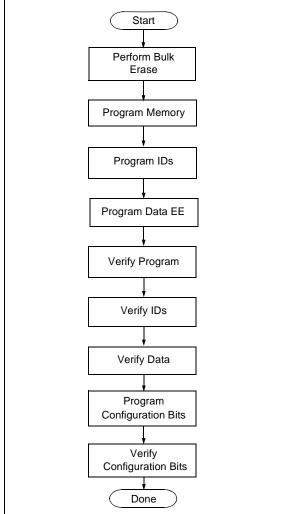

FIGURE 3-3: CONFIGURATION AND ID LOCATIONS FOR PIC18F1XK22/LF1XK22 DEVICES

3.1 High-Level Overview of the Programming Process

Figure 3-4 shows the high-level overview of the programming process. First, a Bulk Erase is performed. Next, the code memory, ID locations and data EEPROM are programmed. These memories are then verified to ensure that programming was successful. If no errors are detected, the Configuration bits are then programmed and verified.

FIGURE 3-4: HIGH-LEVEL PROGRAMMING FLOW

3.2 Entering and Exiting High-Voltage ICSP Program/Verify Mode

As shown in Figure 3-6, the High-Voltage ICSP Program/Verify mode is entered by holding PGC and PGD low and then raising MCLR/VPP/RA3 to VIHH (high voltage). Once in this mode, the code memory, data EEPROM, ID locations and Configuration bits can be accessed and programmed in serial fashion. Figure 3-7 shows the exit sequence.

The sequence that enters the device into the Program/ Verify mode places all unused I/Os in the high-impedance state.

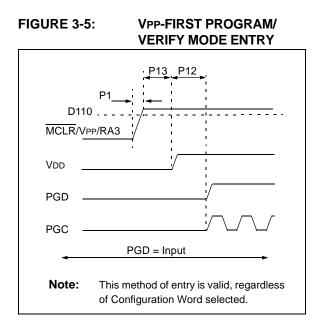

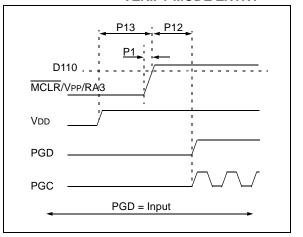

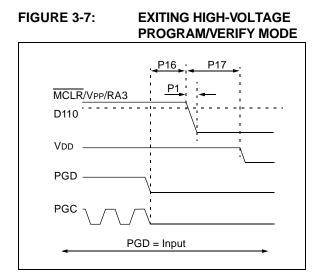

FIGURE 3-6:

VDD-FIRST PROGRAM/ VERIFY MODE ENTRY

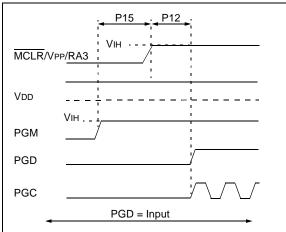

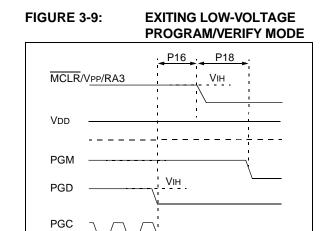

3.3 Entering and Exiting Low-Voltage ICSP Program/Verify Mode

When the LVP Configuration bit is '1' (see **Section 2.1.1.1 "Single-Supply ICSP Programming**"), the Low-Voltage ICSP mode is enabled. As shown in Figure 3-8, Low-Voltage ICSP Program/Verify mode is entered by holding PGC and PGD low, placing a logic high on PGM and then raising MCLR/VPP/RA3 to VIH. In this mode, the RC3/PGM pin is dedicated to the programming function and ceases to be a general purpose I/O pin. Figure 3-9 shows the exit sequence.

The sequence that enters the device into the Program/ Verify mode places all unused I/Os in the high-impedance state.

PGD = Input

3.4 Serial Program/Verify Operation

The PGC pin is used as a clock input pin and the PGD pin is used for entering command bits and data input/ output during serial operation. Commands and data are transmitted on the rising edge of PGC, latched on the falling edge of PGC and are Least Significant bit (LSb) first.

3.4.1 4-BIT COMMANDS

All instructions are 20 bits, consisting of a leading 4-bit command followed by a 16-bit operand, which depends on the type of command being executed. To input a command, PGC is cycled four times. The commands needed for programming and verification are shown in Table 3-2.

Depending on the 4-bit command, the 16-bit operand represents 16 bits of input data or 8 bits of input data and 8 bits of output data.

Throughout this specification, commands and data are presented as illustrated in Table 3-3. The 4-bit command, Most Significant bit (MSb), is shown first. The command operand, or "Data Payload", is shown <MSB><LSB>. Figure 3-10 demonstrates how to serially present a 20-bit command/operand to the device.

3.4.2 CORE INSTRUCTION

The core instruction passes a 16-bit instruction to the CPU core for execution. This is needed to set up registers as appropriate for use with other commands.

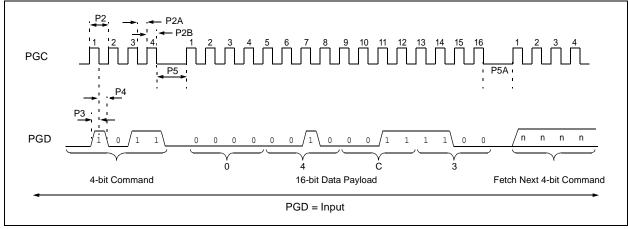

TABLE 3-2:COMMANDS FORPROGRAMMING

Description	4-Bit Command
Core Instruction	0000
(Shift in16-bit instruction)

FIGURE 3-10: TABLE WRITE, POST-INCREMENT TIMING DIAGRAM (1101)

4.0 DEVICE PROGRAMMING

Programming includes the ability to erase or write the various memory regions within the device.

In all cases, except high-voltage ICSP Bulk Erase, the EECON1 register must be configured in order to operate on a particular memory region.

When using the EECON1 register to act on code memory, the EEPGD bit must be set (EECON1<7> = 1) and the CFGS bit must be cleared (EECON1<6> = 0). The WREN bit must be set (EECON1<2> = 1) to enable writes of any sort (e.g., erases) and this must be done prior to initiating a write sequence. The FREE bit must be set (EECON1<4> = 1) in order to erase the program space being pointed to by the Table Pointer. The erase or write sequence is initiated by setting the WR bit (EECON1<1> = 1). It is strongly recommended that the WREN bit only be set immediately prior to a program or erase.

4.1 ICSP Erase

4.1.1 HIGH-VOLTAGE ICSP BULK ERASE

Erasing code or data EEPROM is accomplished by configuring two Bulk Erase Control registers located at 3C0004h and 3C0005h. Code memory may be erased portions at a time, or the user may erase the entire device in one action. Bulk Erase operations will also clear any code-protect settings associated with the memory block erased. Erase options are detailed in Table 4-1. If data EEPROM is code-protected (CPD = 0), the user must request an erase of data EEPROM (e.g., 00008484h as shown in Table 4-1).

TABLE 4-1: BULK ERASE OPTIONS	
-------------------------------	--

Description	Data (3C0005h:3C0004h)	
Chip Erase	0F0F8787h	
Erase Data EEPROM	00008484h	
Erase Boot Block	00008181h	
Erase Config Bits	00008282h	
Erase Code EEPROM Block 0	01018080h	
Erase Code EEPROM Block 1	02028080h	
Erase Code EEPROM Block 2	04048080h	
Erase Code EEPROM Block 3	08088080h	

The actual Bulk Erase function is a self-timed operation. Once the erase has started (falling edge of the 4th PGC after the NOP command), serial execution will cease until the erase completes (parameter P11). During this time, PGC may continue to toggle but PGD must be held low.

The code sequence to erase the entire device is shown in Table 4-2 and the flowchart is shown in Figure 4-1.

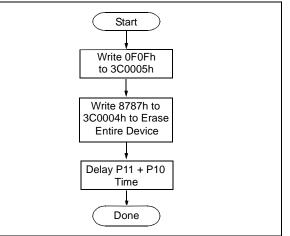

Note: A Bulk Erase is the only way to reprogram code-protect bits from an "on" state to an "off" state.

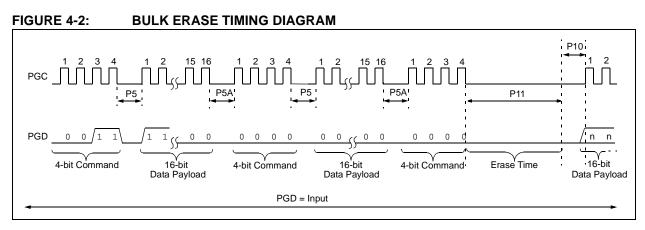

TABLE 4-2: BULK ERASE COMMAND SEQUENCE

OLQOLIIOL				
4-Bit Command	Data Payload	Core Instruction		
0000	0E 3C	MOVLW 3Ch		
0000	6E F8	MOVWF TBLPTRU		
0000	0E 00	MOVLW 00h

0000	00 00	NOP		
0000	00 00	Hold PGD low until erase completes.		

FIGURE 4-1:

BULK ERASE FLOW

4.1.2 LOW-VOLTAGE ICSP BULK ERASE

When using low-voltage ICSP, the part must be supplied by the voltage specified in parameter D111 if a Bulk Erase is to be executed. All other Bulk Erase details as described above apply.

If it is determined that a program memory erase must be performed at a supply voltage below the Bulk Erase limit, refer to the erase methodology described in Section 4.1.3 "ICSP Row Erase" and Section 4.2.1 "Modifying Code Memory".

If it is determined that a data EEPROM erase must be performed at a supply voltage below the Bulk Erase limit, follow the methodology described in **Section 4.3 "Data EEPROM Programming"** and write '1's to the array.

4.1.3 ICSP ROW ERASE

Regardless of whether high or low-voltage ICSP is used, it is possible to erase one row (64 bytes of data), provided the block is not code or write-protected. Rows are located at static boundaries beginning at program memory address 000000h, extending to the internal program memory limit (see **Section 3.0 "Memory Maps"**).

The Row Erase duration is self-timed. After the WR bit in EECON1 is set, two NOPs are issued. Erase starts upon the 4th PGC of the second NOP. It ends when the WR bit is cleared by hardware.

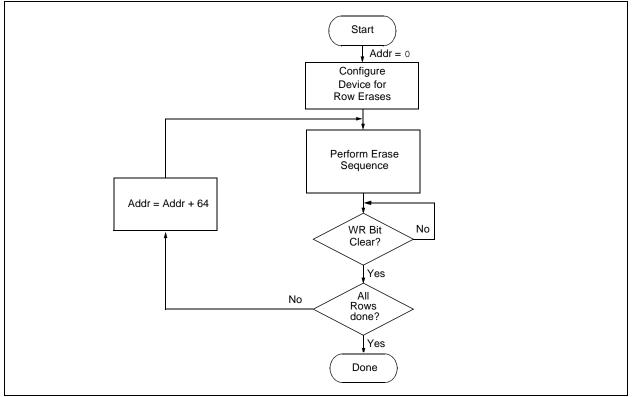

The code sequence to Row Erase a PIC18F1XK22/ LF1XK22 device is shown in Table 4-3. The flowchart shown in Figure 4-3 depicts the logic necessary to completely erase the PIC18F1XK22/LF1XK22 devices. The timing diagram for Row Erase is identical to the data EEPROM write timing shown in Figure 4-7.

Note: The TBLPTR register can point at any byte within the row intended for erase.

Note 1: See Figure 5-4 for details on shift out data timing.

4.2 Code Memory Programming

Programming code memory is accomplished by first loading data into the write buffer and then initiating a programming sequence. The write and erase buffer sizes shown in Table 4-4 can be mapped to any location of the same size beginning at 000000h. The actual memory write sequence takes the contents of this buffer and programs the proper amount of code memory that contains the Table Pointer.

The programming duration is externally timed and is controlled by PGC. After a Start Programming command is issued (4-bit command, '1111'), a NOP is issued, where the 4th PGC is held high for the duration of the programming time, P9.

After PGC is brought low, the programming sequence is terminated. PGC must be held low for the time specified by parameter P10 to allow high-voltage discharge of the memory array.

The code sequence to program a PIC18F1XK22/ LF1XK22 device is shown in Table 4-5. The flowchart shown in Figure 4-4 depicts the logic necessary to completely write a PIC18F1XK22/LF1XK22 device. The timing diagram that details the Start Programming command and parameters P9 and P10 is shown in Figure 4-5.

Note: The TBLPTR register must point to the same region when initiating the programming sequence as it did when the write buffers were loaded.

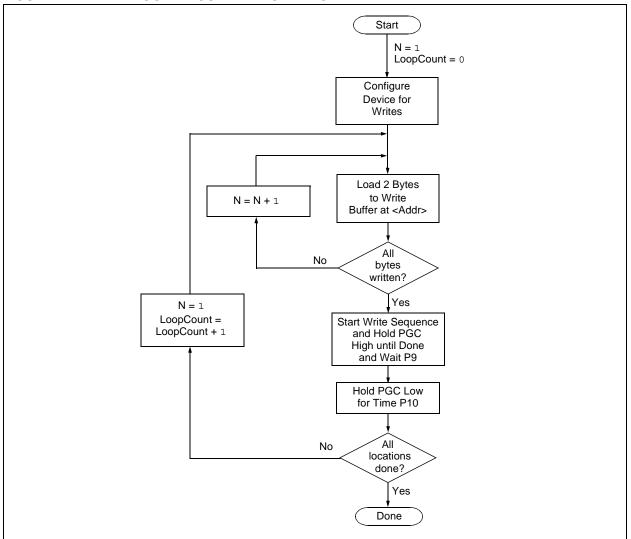

TABLE 4-4:WRITE AND ERASE BUFFER SIZES

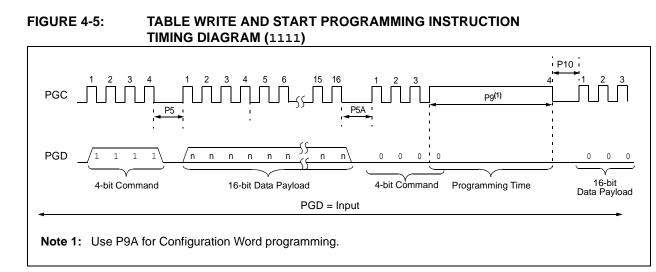

Devices	Write Buffer Size (bytes)	Erase Size (bytes)
PIC18F14K22	16	64
PIC18F13K22	8	64

TABLE 4-5: WRITE CODE MEMORY CODE SEQUENCE

4-bit Command	Data Payload	Core Instruction						
Step 1: Direct ad	Step 1: Direct access to code memory.

To continue writi the loop.	To continue writing data, repeat steps 2 through 4, where the Address Pointer is incremented by 2 at each iteration of the loop.							

4.2.1 MODIFYING CODE MEMORY

The previous programming example assumed that the device has been Bulk Erased prior to programming (see **Section 4.1.1 "High-Voltage ICSP Bulk Erase"**). It may be the case, however, that the user wishes to modify only a section of an already programmed device.

The appropriate number of bytes required for the erase buffer must be read out of code memory (as described in **Section 5.2 "Verify Code Memory and ID Locations"**) and buffered. Modifications can be made on this buffer. Then, the block of code memory that was read out must be erased and rewritten with the modified data.

The WREN bit must be set if the WR bit in EECON1 is used to initiate a write sequence.

4-bit Command	Data Payload Core Instruction

Step 8: Disable w	rites.					

TABLE 4-6: MODIFYING CODE MEMORY

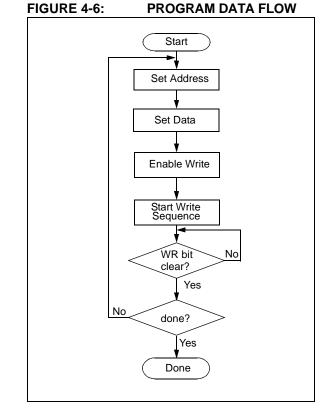

4.3 Data EEPROM Programming

Data EEPROM is accessed one byte at a time via an Address Pointer (register EEADR) and a data latch (EEDATA). Data EEPROM is written by loading EEADR with the desired memory location, EEDATA with the data to be written and initiating a memory write by appropriately configuring the EECON1 register. A byte write automatically erases the location and writes the new data (erase-before-write).

When using the EECON1 register to perform a data EEPROM write, both the EEPGD and CFGS bits must be cleared (EECON1<7:6> = 00). The WREN bit must be set (EECON1<2> = 1) to enable writes of any sort and this must be done prior to initiating a write sequence. The write sequence is initiated by setting the WR bit (EECON1<1> = 1).

The write begins on the falling edge of the 24th PGC after the WR bit is set. It ends when the WR bit is cleared by hardware.

After the programming sequence terminates, PGC must be held low for the time specified by parameter P10 to allow high-voltage discharge of the memory array.

Repeat steps 2	through 8 to write more of	data.					

TABLE 4-7: PROGRAMMING DATA MEMORY

Note 1: See Figure 5-4 for details on shift out data timing.

4.4 ID Location Programming

The ID locations are programmed much like the code memory. The ID registers are mapped in addresses 200000h through 200007h. These locations read out normally even after code protection.

Note:	The user only needs to fill the first 8 bytes
	of the write buffer in order to write the ID
	locations.

Table 4-8 demonstrates the code sequence required to	
write the ID locations.	

In order to modify the ID locations, refer to the methodology described in **Section 4.2.1** "**Modifying Code Memory**". As with code memory, the ID locations must be erased before being modified.

4-bit Command	Data Payload	Core Instruction				
Step 1: Direct ad	ccess to code memory.					
0000	8E A6	BSF EECON1, EEPGD				
0000	9C A6	BCF EECON1, CFGS

TABLE 4-8: WRITE ID SEQUENCE

4.5 Boot Block Programming

The code sequence detailed in Table 4-5 should be used, except that the address used in "Step 2" will be in the following ranges:

If BBSIZ = 0:

000000h-0003FFh for PIC18F13K22/LF13K22 000000h-0007FFh for PIC18F14K22/LF14K22

If BBSIZ = 1:

000000h-0007FFh for PIC18F13K22/LF13K22 000000h-000FFFh for PIC18F14K22/LF14K22

4.6 Configuration Bits Programming

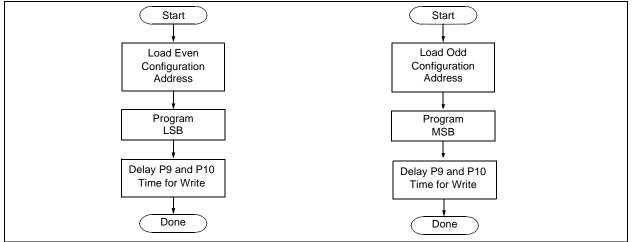

Unlike code memory, the Configuration bits are programmed a byte at a time. The Table Write, Begin Programming 4-bit command ('1111') is used, but only 8 bits of the following 16-bit payload will be written. The LSB of the payload will be written to even addresses and the MSB will be written to odd addresses. The code sequence to program two consecutive configuration locations is shown in Table 4-9. See Figure 4-5 for the timing diagram.

Note: The address must be explicitly written for each byte programmed. The addresses can not be incremented in this mode.

4-bit Command	Data Payload	Core Instruction				
Step 1: Direct access to configuration memory.						
0000	8E A6	BSF EECON1, EEPGD				
0000	8C A6	BSF EECON1, CFGS				
0000	84 A6	BSF EECON1, WREN				
Step 2(1): Set Ta	able Pointer for configuration	tion byte to be written. Write even/odd addresses.				
0000	0E 30	MOVLW 30h				
0000	6E F8	MOVWF TBLPTRU				
0000	0E 00	MOVLW 00h				
0000	6E F7	MOVWF TBLPRTH				
0000	0E 00	MOVLW 00h				
0000	6E F6	MOVWF TBLPTRL				
1111	<msb ignored=""><lsb></lsb></msb>	Load 2 bytes and start programming.				
0000	00 00	NOP - hold PGC high for time P9 and low for time P10.				
0000	0E 01	MOVLW 01h				
0000	6E F6	MOVWF TBLPTRL				
1111	<msb><lsb ignored=""></lsb></msb>	Load 2 bytes and start programming.				
0000	00 00	NOP - hold PGC high for time P9A and low for time P10.				

Note 1: Enabling the write protection of Configuration bits (WRTC = 0 in CONFIG6H) will prevent further writing of Configuration bits. Always write all the Configuration bits before enabling the write protection for Configuration bits.

FIGURE 4-8: CONFIGURATION PROGRAMMING FLOW

5.0 READING THE DEVICE

5.1 Read Code Memory, ID Locations and Configuration Bits

Code memory is accessed one byte at a time via the 4-bit command, '1001' (table read, post-increment). The contents of memory pointed to by the Table Pointer (TBLPTRU:TBLPTRH:TBLPTRL) are serially output on PGD.

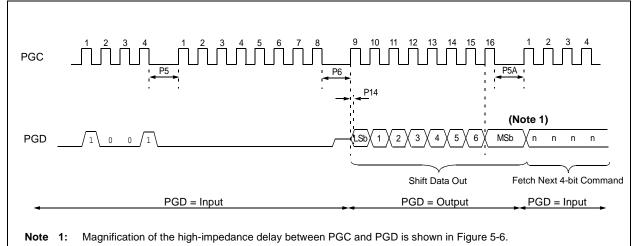

The 4-bit command is shifted in LSb first. The read is executed during the next 8 clocks, then shifted out on PGD during the last 8 clocks, LSb to MSb. A delay of P6 must be introduced after the falling edge of the 8th PGC of the operand to allow PGD to transition from an input to an output. During this time, PGC must be held low (see Figure 5-1). This operation also increments the Table Pointer by one, pointing to the next byte in code memory for the next read.

This technique will work to read any memory in the 000000h to 3FFFFFh address space, so it also applies to the reading of the ID and Configuration registers.

4-bit Command	Data Payload	Core Instruction	
Step 1: Set Ta	ble Pointer		
0000	0E <addr[21:16]></addr[21:16]>	MOVLW Addr[21:16]	
0000	6E F8	MOVWF TBLPTRU	
0000	0E <addr[15:8]></addr[15:8]>	MOVLW <addr[15:8]></addr[15:8]>	
0000	6E F7	MOVWF TBLPTRH	
0000	0E <addr[7:0]></addr[7:0]>	MOVLW <addr[7:0]></addr[7:0]>	
0000	6E F6	MOVWF TBLPTRL	
Step 2: Read r	memory and then shift ou	t on PGD, LSb to MSb	
1001	00 00	TBLRD *+	

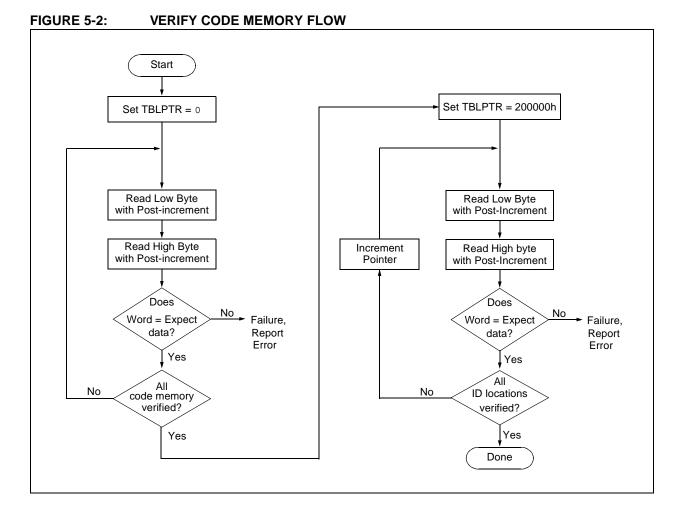

TABLE 5-1: READ CODE MEMORY SEQUENCE

FIGURE 5-1: TABLE READ POST-INCREMENT INSTRUCTION TIMING DIAGRAM (1001)

5.2 Verify Code Memory and ID Locations

The verify step involves reading back the code memory space and comparing it against the copy held in the programmer's buffer. Memory reads occur a single byte at a time, so two bytes must be read to compare against the word in the programmer's buffer. Refer to **Section 5.1 "Read Code Memory, ID Locations and Configuration Bits"** for implementation details of reading code memory. The Table Pointer must be manually set to 20000h (base address of the ID locations) once the code memory has been verified. The post-increment feature of the table read 4-bit command can not be used to increment the Table Pointer beyond the code memory space. In a 64-Kbyte device, for example, a post-increment read of address FFFFh will wrap the Table Pointer back to 000000h, rather than point to unimplemented address, 010000h.

5.3 Verify Configuration Bits

A configuration address may be read and output on PGD via the 4-bit command, '1001'. Configuration data is read and written in a byte-wise fashion, so it is not necessary to merge two bytes into a word prior to a compare. The result may then be immediately compared to the appropriate configuration data in the programmer's memory for verification. Refer to **Section 5.1 "Read Code Memory, ID Locations and Configuration Bits"** for implementation details of reading configuration data.

5.4 Read Data EEPROM Memory

Data EEPROM is accessed one byte at a time via an Address Pointer (register EEADR) and a data latch (EEDATA). Data EEPROM is read by loading EEADR with the desired memory location and initiating a memory read by appropriately configuring the EECON1 register. The data will be loaded into EEDATA, where it may be serially output on PGD via the 4-bit command, '0010' (Shift Out Data Holding register). A delay of P6 must be introduced after the falling edge of the 8th PGC of the operand to allow PGD to transition from an input to an output. During this time, PGC must be held low (see Figure 5-4).

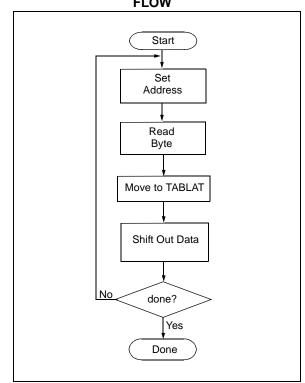

The command sequence to read a single byte of data is shown in Table 5-2.

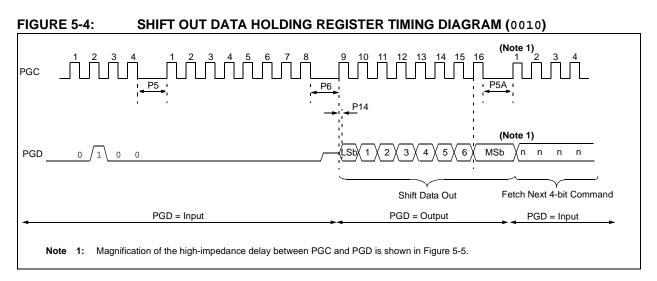

4-bit Command	Data Payload	Core Instruction				
Step 1: Direct acc	cess to data EEPROM.					
0000 0000	9E A6 9C A6	BCF EECON1, EEPGD BCF EECON1, CFGS				
Step 2: Set the da	ata EEPROM Address Poi	nter.				
0000 0000 Step 3: Initiate a 1	0E <addr> 6E A9</addr>	MOVLW <addr> MOVWF EEADR</addr>				
0000 80 A6		BSF EECON1, RD				
Step 4: Load data	a into the Serial Data Holdi	ng register.				
0000 0000 0000 0010	50 A8 6E F5 00 00 <msb><lsb></lsb></msb>	MOVF EEDATA, W, O MOVWF TABLAT NOP Shift Out Data ⁽¹⁾				

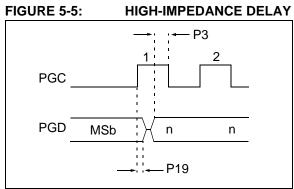

TABLE 5-2: READ DATA EEPROM MEMORY

Note 1: The <LSB> is undefined. The <MSB> is the data.

FIGURE 5-3: READ DATA EEPROM FLOW

5.5 Verify Data EEPROM

A data EEPROM address may be read via a sequence of core instructions (4-bit command, '0000') and then output on PGD via the 4-bit command, '0010' (TABLAT register). The result may then be immediately compared to the appropriate data in the programmer's memory for verification. Refer to **Section 5.4 "Read Data EEPROM Memory"** for implementation details of reading data EEPROM.

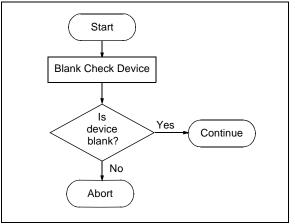

5.6 Blank Check

The term "Blank Check" means to verify that the device has no programmed memory cells. All memories must be verified: code memory, data EEPROM, ID locations and Configuration bits. The device ID registers (3FFFFEh:3FFFFFh) should be ignored.

A "blank" or "erased" memory cell will read as a '1'. Therefore, Blank Checking a device merely means to verify that all bytes read as FFh except the Configuration bits. Unused (reserved) Configuration bits will read '0' (programmed). Refer to Table 6-1 for blank configuration expect data for the various PIC18F1XK22/ LF1XK22 devices.

Given that Blank Checking is merely code and data EEPROM verification with FFh expect data, refer to Section 5.4 "Read Data EEPROM Memory" and Section 5.2 "Verify Code Memory and ID Locations" for implementation details.

6.0 CONFIGURATION WORD

The PIC18F1XK22/LF1XK22 devices have several Configuration Words. These bits can be set or cleared to select various device configurations. All other memory areas should be programmed and verified prior to setting Configuration Words. These bits may be read out normally, even after read or code protection. See Table 6-1 for a list of Configuration bits and device IDs and Table 6-3 for the Configuration bit descriptions.

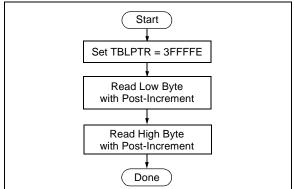

6.1 ID Locations

A user may store identification information (ID) in eight ID locations mapped in 200000h:200007h. It is recommended that the Most Significant nibble of each ID be Fh. In doing so, if the user code inadvertently tries to execute from the ID space, the ID data will execute as a NOP.

6.2 Device ID Word

The device ID word for the PIC18F1XK22/LF1XK22 devices is located at 3FFFEh:3FFFFh. These bits may be used by the programmer to identify what device type is being programmed and read out normally, even after code or read protection. See Table 6-2 for a complete list of device ID values.

TABLE 6-3: PIC18F1XK22/LF1XK22 BIT DESCRIPTIONS (CONTINUED)

7.0 EMBEDDING CONFIGURATION WORD INFORMATION IN THE HEX FILE

To allow portability of code, a PIC18F1XK22/LF1XK22 programmer is required to read the Configuration Word locations from the hex file. If Configuration Word information is not present in the hex file, then a simple warning message should be issued. Similarly, while saving a hex file, all Configuration Word information must be included. An option to not include the Configuration Word information may be provided. When embedding Configuration Word information in the hex file, it should start at address 300000h.

Microchip Technology Inc. feels strongly that this feature is important for the benefit of the end customer.

7.1 Embedding Data EEPROM Information In the HEX File

To allow portability of code, a PIC18F1XK22/LF1XK22 programmer is required to read the data EEPROM information from the hex file. If data EEPROM information is not present, a simple warning message should be issued. Similarly, when saving a hex file, all data EEPROM information must be included. An option to not include the data EEPROM information may be provided. When embedding data EEPROM information in the hex file, it should start at address F00000h.

Microchip Technology Inc. believes that this feature is important for the benefit of the end customer.

7.2 Checksum Computation

The checksum is calculated by summing the following:

- The contents of all code memory locations
- The Configuration Word, appropriately masked
- ID locations (Only if any portion of program memory is code-protected)

The Least Significant 16 bits of this sum are the checksum.

Code protection limits access to program memory by both external programmer (code-protect) and code execution (table read protect). The ID locations, when included in a code protected checksum, contain the checksum of an unprotected part. The unprotected checksum is distributed: one nibble per ID location. Each nibble is right justified. Table 7-1 describes how to calculate the checksum for each device.

Note: The checksum calculation differs depending on the code-protect setting. Since the code memory locations read out differently depending on the code-protect setting, the table describes how to manipulate the actual code memory values to simulate the values that would be read from a protected device. When calculating a checksum by reading a device, the entire code memory can simply be read and summed. The Configuration Word and ID locations can always be read.

TABLE 7-1: CHECKSUM COMPUTATION

Device	Device Code-Protect Checksum BBSIZ = 0		Blank Value	0xAA at 0 and Max Address

P2A	TPGCL	Serial Clock (PGC) Low Time	40		ns	VDD = 3.6V
			400		ns	VDD = 1.8V
P2B	Трдсн	Serial Clock (PGC) High Time	40	_	ns	VDD = 3.6V
			400		ns	VDD = 1.8V
P3	TSET1	Input Data Setup Time to Serial Clock \downarrow	15	_	ns	
P4	THLD1	Input Data Hold Time from PGC \downarrow	15	—	ns	
P5	TDLY1	Delay between 4-bit Command and Command Operand	40	—	ns	
P5A	TDLY1A	Delay between 4-bit Command Operand and next 4-bit Command	40	—	ns	
P6	TDLY2	Delay between Last PGC \downarrow of Command Byte to First PGC \uparrow of Read of Data Word	20	—	ns	
P9	TDLY5	PGC High Time (minimum programming time)	1	—	ms	Externally Timed
P9A	Tdly5a	PGC High Time	5		ms	Configuration Word programming time
P10	TDLY6	PGC Low Time after Programming (high-voltage discharge time)	100	—	μS	
P11	Tdly7	Delay to allow Self-Timed Data Write or Bulk Erase to occur	5	—	ms	
P11A	TDRWT	Data Write Polling Time	4	—	ms	

Note 1: Do not allow excess time when transitioning MCLR between VIL and VIHH; this can cause spurious program executions to occur. The maximum transition time is:

1 TCY + TPWRT (if enabled) + 1024 Tosc (for LP, HS, HS/PLL and XT modes only) + 2 ms (for HS/PLL mode only) + 1.5 μs (for EC mode only) where TCY is the instruction cycle time, TPWRT is the Power-up Timer period and Tosc is the oscillator period. For specific values, refer to the Electrical Characteristics section of the device data sheet for the particular device.

8.0 AC/DC CHARACTERISTICS TIMING REQUIREMENTS FOR PROGRAM/ VERIFY TEST MODE (CONTINUED)

Standard Operating Conditions Operating Temperature: 25°C is recommended						
Param No.	Sym.	Characteristic	Min.	Max.	Units	Conditions
P12	Thld2	Input Data Hold Time from MCLR/VPP/RA3 ↑	2	—	μS	
P12A	Thld2a	Input Data Hold Time from MCLR/VPP/RA3 1	70	_	μS	PIC18F1XK22 Only. Refer to Figure 2.1.1.
P13	TSET2	VDD ↑ Setup Time to MCLR/VPP/RA3 ↑	100	—	ns	
P13A	TSET2A	VDD ↑ Setup Time to MCLR/VPP/RA3 ↑	70	—	μS	PIC18F1XK22 Only. Refer to Figure 2.1.1.
P14	TVALID	Data Out Valid from PGC ↑	10	_	ns	
P15	TSET3	PGM ↑ Setup Time to MCLR/VPP/RA3 ↑	2	—	μS	
P16	TDLY8	Delay between Last PGC \downarrow and $\overline{\mathrm{MCLR}}/\mathrm{VPP/RA3}\downarrow$	0	—	S	
P17	THLD3	MCLR/VPP/RA3 ↓ to VDD ↓	_	100	ns	
P18	Thld4	MCLR/VPP/RA3 ↓ to PGM ↓	0	_	S	
P19	Thiz	Delay from PGC ↑ to PGD High-Z	3	10	nS	
P20	Tppdp	Hold time after VPP changes	5	—	μS	

Note 1: Do not allow excess time when transitioning MCLR between VIL and VIHH; this can cause spurious program executions to occur. The maximum transition time is:

1 TCY + TPWRT (if enabled) + 1024 Tosc (for LP, HS, HS/PLL and XT modes only) + 2 ms (for HS/PLL mode only) + 1.5 μ s (for EC mode only) where TCY is the instruction cycle time, TPWRT is the Power-up Timer period and Tosc is the oscillator period. For specific values, refer to the Electrical Characteristics section of the device data sheet for the particular device.

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

Trademarks

The Microchip name and logo, the Microchip logo, Accuron, dsPIC, KEELOQ, KEELOQ logo, MPLAB, PIC, PICmicro, PICSTART, rfPIC, SmartShunt and UNI/O are registered trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

FilterLab, Linear Active Thermistor, MXDEV, MXLAB, SEEVAL, SmartSensor and The Embedded Control Solutions Company are registered trademarks of Microchip Technology Incorporated in the U.S.A.

Analog-for-the-Digital Age, Application Maestro, CodeGuard, dsPICDEM, dsPICDEM.net, dsPICworks, dsSPEAK, ECAN, ECONOMONITOR, FanSense, In-Circuit Serial Programming, ICSP, ICEPIC, Mindi, MiWi, MPASM, MPLAB Certified logo, MPLIB, MPLINK, mTouch, PICkit, PICDEM, PICDEM.net, PICtail, PIC³² logo, PowerCal, PowerInfo, PowerMate, PowerTool, REAL ICE, rfLAB, Select Mode, Total Endurance, WiperLock and ZENA are trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

SQTP is a service mark of Microchip Technology Incorporated in the U.S.A.

QUALITY MANAGEMENT SYSTEM CERTIFIED BY DNV ISO/TS 16949:2002

Microchip received ISO/TS-16949:2002 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KEEL00® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
